

C-lens-pos R-2 — the G-group measurements (352 of 700), in relative coordinates

G group only (n_prompt = 501); W group has no prompt/generation split and stays in absolute coordinates

attribution diagnostic — the decision table is NOT re-applied here; the 10% / 30% lines are drawn for reference only

L1 only — measured values; the reading belongs to the judgement layer.

Buckets and this frame were frozen in PREREG_r2_relative_coordinates_20260802 before any aggregation was computed.

FLAG-lens-pos-domain is now a standing clause: C-lens-pos found the deep-position seat readout has no verifiable anchor (B6 out of domain; B4/B5 beyond 0.30 digits). Three confounds stand with the verdict: W group does not degrade with position, the G buckets straddle the prompt/generation boundary, and the bridge term varied attention implementation and sequence length together.
